**OPTIMIZING FLIGHT BOOKING
DECISIONS THROUGH
MACHINE LEARNING
PRICE PREDICTIONS**

DONE BY

K.SOWMIYA

G.NIVETHA GNANAPOO

S.MAHESWARI

G.POOPATHI

INTRODUCTION

1.1 Overviews:

The Flight ticket prices increase or decrease every now and then depending on various factors like timing of the flights, destination, duration of flights.

In the proposed system a predictive model will be created by applying machine learning algorithms to the collected historical data of flights.

The process of flight booking price prediction using machine learning typically involves the following the steps:

1. Data Collection: Historical data on flight prices and other relevant factors, such as the time of year, destination, and airline, are collected from various sources.

2. Data Preprocessing: The collected data is cleaned and processed to remove any missing values, outliers, or errors that may affect the accuracy of the model.

3. Feature Engineering: Relevant features are identified and extracted from the data to be used as inputs to the machine learning algorithm. For example, features such as the departure and arrival airports, flight date and time, and airline can be used to predict flight prices.

4. Model Training: The preprocessed data is used to train the machine learning algorithm. Various algorithms can be used for this purpose, such as regression models, decision trees, and neural networks.

5. Model Evaluation: The trained model is tested on a separate dataset to evaluate its

accuracy and performance. Different metrics such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and R-squared can be used to evaluate the model's performance.

6. Model Deployment: Once the model is trained and evaluated, it can be deployed to predict the prices of future flights. The model can be integrated into travel booking websites or travel agencies to assist customers in finding the best deals on flights.

Flight booking price prediction using machine learning can help customers save money by predicting the optimal time to book a flight, and it can also help airlines optimize their pricing strategies to increase revenue.

A Brief Description about Project:

People who work frequently travel through flight will have better knowledge on best discount and right time to buy the ticket.

For the business purpose many airline companies change prices according to the seasons or time duration. They will increase the price when people travel more. Estimating the highest prices of the airlines data for the route is collected with features such as Duration, Source, Destination, Arrival and Departure.

Features are taken from chosen dataset and in the price wherein the airline price ticket costs vary overtime. we have implemented flight price prediction for users by using KNN, decision tree and random forest algorithms. Random Forest shows the best accuracy of 80% for predicting the flight price. also, we have done correlation tests and metrics for the statistical analysis.

1.2 Purpose:

The purpose of building a flight price prediction model using machine learning is help users make informed decisions about their travel plans by providing them with accurate and timely predictions of flight prices.

This can benefits users in various ways, such as saving money, by predicting flight prices in advance, users can make more informed decisions about when to book their flights, potentially saving money on their travel expenses.

Planning Travel: Users can plan their travel in advance, knowing when and where they can get the best deals on flights, making their travel planning more convenient.

Avoiding Last-Minute Price Hikes: With the help of the flight price prediction model, users can avoid last-minute price hikes that may occur due to increased demand or other factors.

Business Travel: Business travelers can use the model to optimize their travel budget and make

informed decisions about when to book their flights.

Overall, building a flight price prediction model using machine learning can provide valuable insights to users, help them save money, and make their travel planning more convenient and efficient.

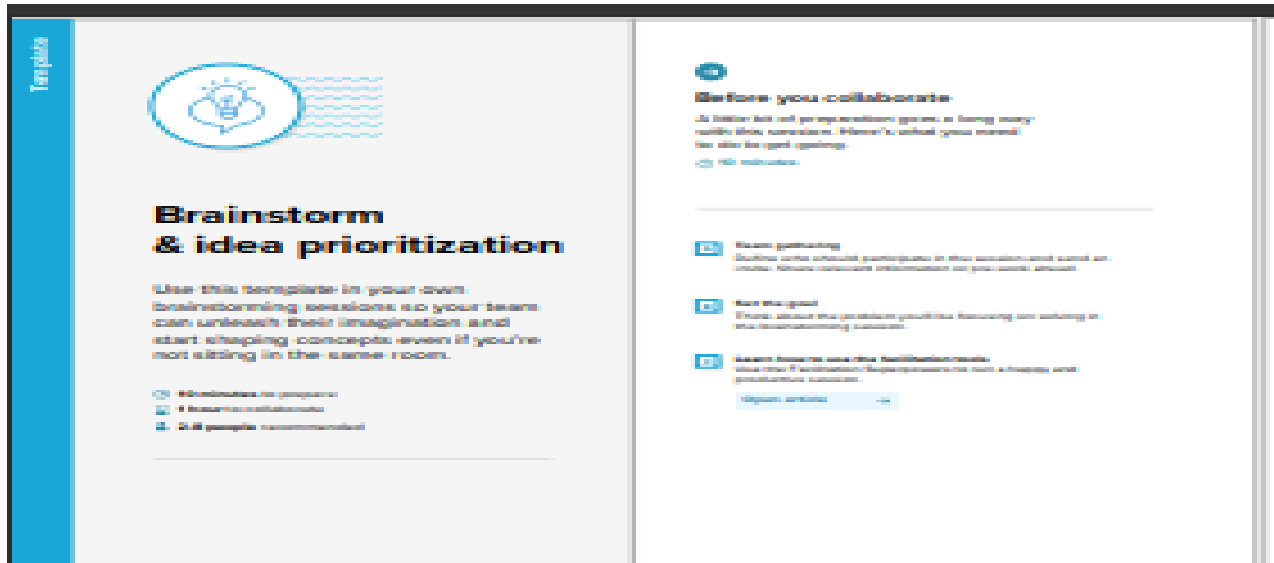

Problem Definition & Design Thinking

2.1 Empathy Map

2.2 Ideation & Brainstorming Map

Person 1

machine learning lies in the 'Aviation industry' to predict the prices of flights.

The flight ticket prices increase or decrease every year and then, depending on various factors like timing of the flight, destination, duration of flight.

This pattern to make the predictions in future, automating the process and making the process quicker.

In the proposed system a predictive model will be created by applying machine learning algorithms to the collected historical data of flights.

Person 2

After price prediction using machine learning techniques and threshold collected and used to train machine learning model.

They have used various algorithms such as Multiple Regression (MR), Decision Regression, Neural Network, Support Vector Machine (SVM), Random Forest Regression Tree, and general artificial neural network for machine learning algorithm.

Random forest can be used as both regression tasks (predict continuous features, such as price) or classification tasks (predict categorical or discrete output).

Random forest is both a supervised learning algorithm and an ensemble algorithm. It is supervised in the sense that during training it learns the mappings between inputs and outputs.

Person 3

The training set and test set Data sets. The training set contains the features, along with the prices of the flights.

Many features are the Data sets like Airline, Date of Journey, Source, Destination, etc. The source has which the source begins.

They have tried and trained various types of models with removing and adding different features from the dataset.

These factors help create a pattern to decide the price of a flight.

Person 4

There are various factors/features which impact the prices of flights – distance, flight time, number of stops etc.

The first thing we do is to create a list of categorical columns, and check the unique values present in these columns.

The data also has two basic categories of airline carriers operating in India – the economical group and the luxury group, that they used for the data sets.

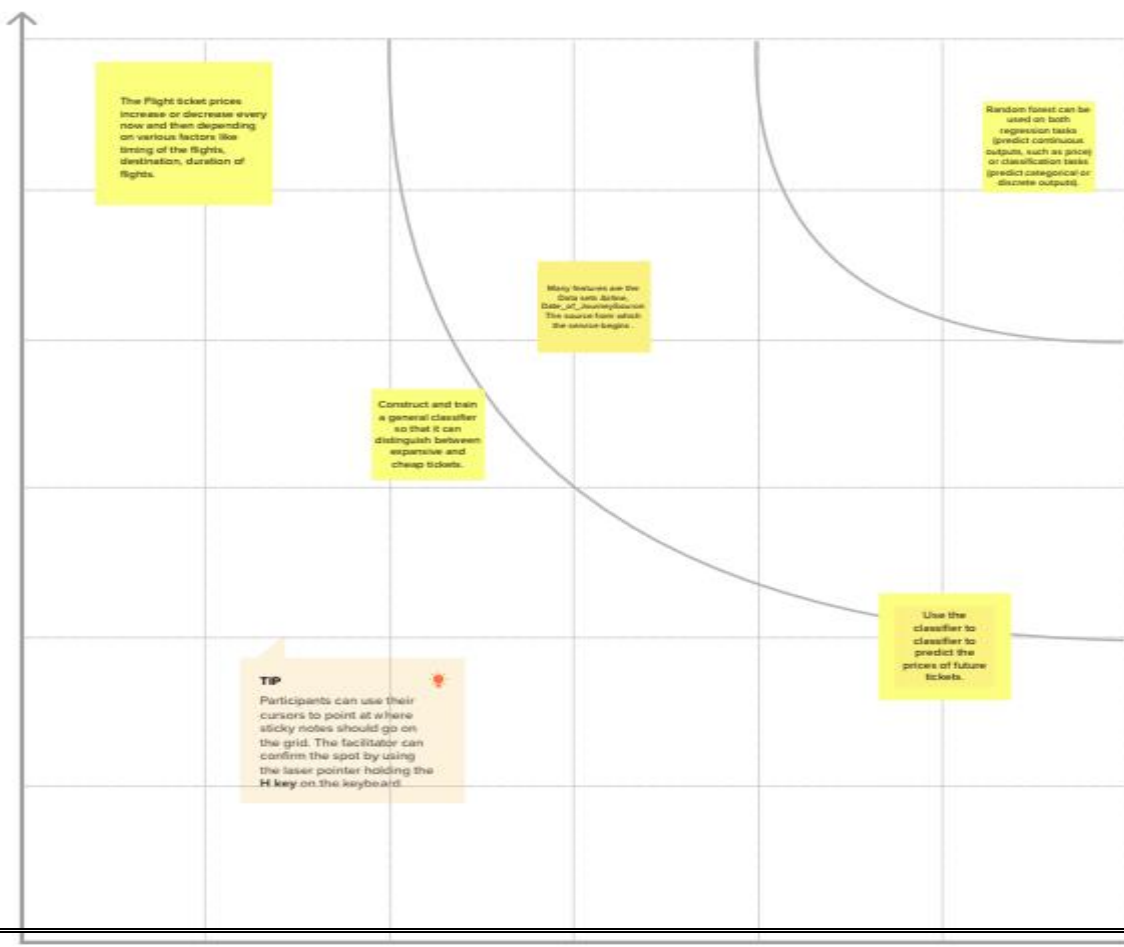

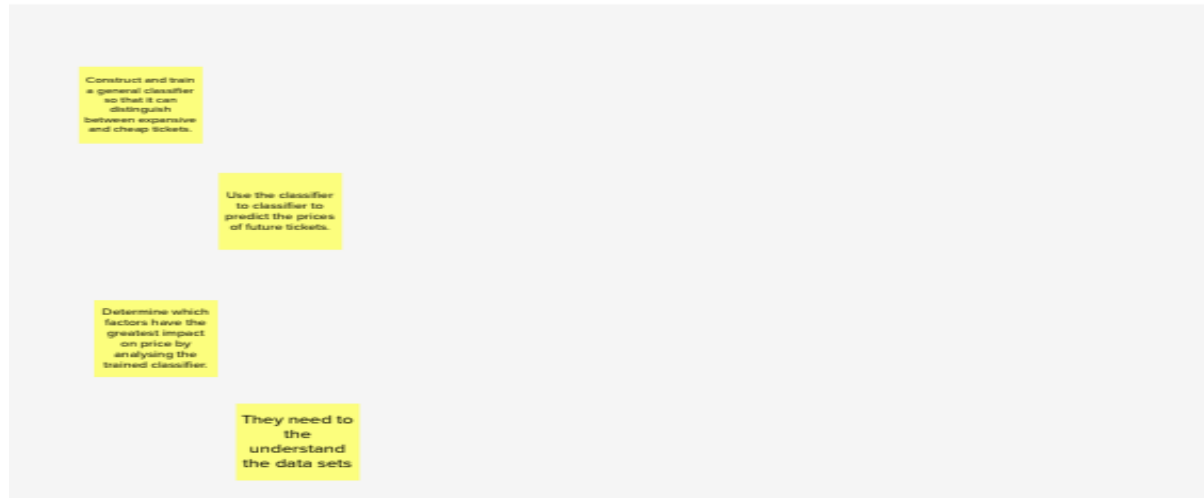

Followed typical data science life cycle. The best results came from Bagging regression tree.

3

Group ideas

Take turns sharing your ideas while clustering similar or related notes as you go. Once all sticky notes have been grouped, give each cluster a sentence-like label. If a cluster is bigger than six sticky notes, try and see if you and break it up into smaller sub-groups.

🕒 20 minutes

Results:

Importing required libraries:

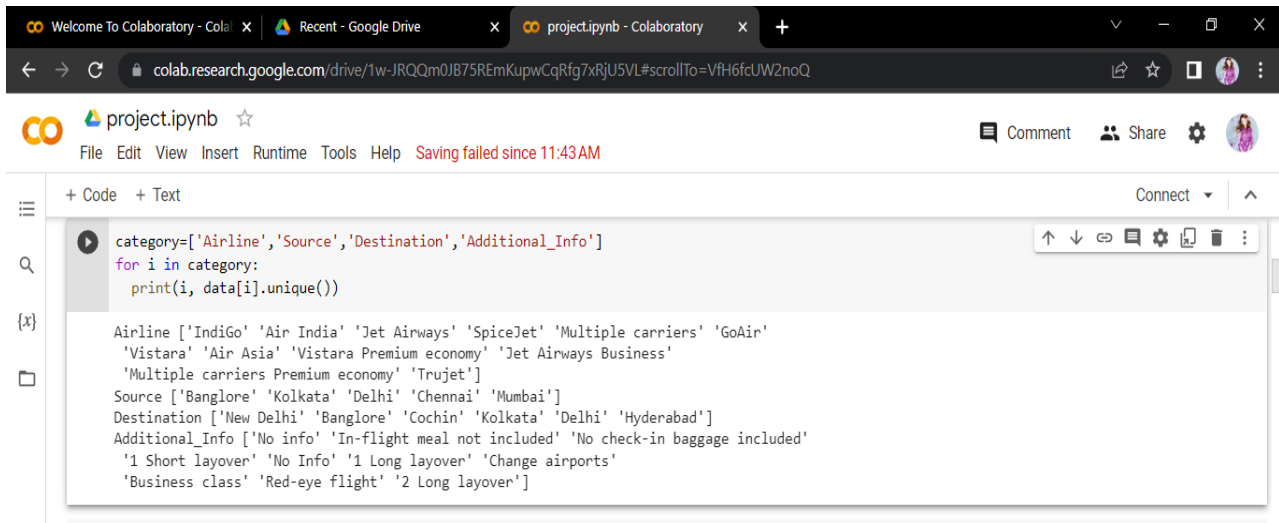

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
from sklearn.model_selection import train_test_split
from sklearn.ensemble import RandomForestClassifier, GradientBoostingClassifier
from sklearn.ensemble import RandomForestRegressor, GradientBoostingRegressor, AdaBoostRegressor
from sklearn.tree import DecisionTreeClassifier
from sklearn.neighbors import KNeighborsClassifier
from sklearn.metrics import f1_score
from sklearn.metrics import classification_report, confusion_matrix
import warnings
import pickle
from scipy import stats
import imblearn
from imblearn.over_sampling import SMOTE
warnings.filterwarnings('ignore')
plt.style.use('fivethirtyeight')
from google.colab import drive
drive.mount("/content/gdrive")
```

Read the excel file:

```
[ ] import io
import pandas as pd
data=pd.read_excel('Data_Train.xlsx')
data.head()
```

	Airline	Date_of_Journey	Source	Destination	Route	Dep_Time	Arrival_Time	Duration	Total_Stops	Additional_Info	Price
0	IndiGo	24/03/2019	Banglore	New Delhi	BLR → DEL	22:20	01:10 22 Mar	2h 50m	non-stop	No info	3897
1	Air India	1/05/2019	Kolkata	Banglore	CCU → IXR → BBI → BLR	05:50	13:15	7h 25m	2 stops	No info	7662
2	Jet Airways	9/06/2019	Delhi	Cochin	DEL → LKO → BOM → COK	09:25	04:25 10 Jun	19h	2 stops	No info	13882
3	IndiGo	12/05/2019	Kolkata	Banglore	CCU → NAG → BLR	18:05	23:30	5h 25m	1 stop	No info	6218
4	IndiGo	01/03/2019	Banglore	New Delhi	BLR → NAG → DEL	16:50	21:35	4h 45m	1 stop	No info	13302

Handling the category:

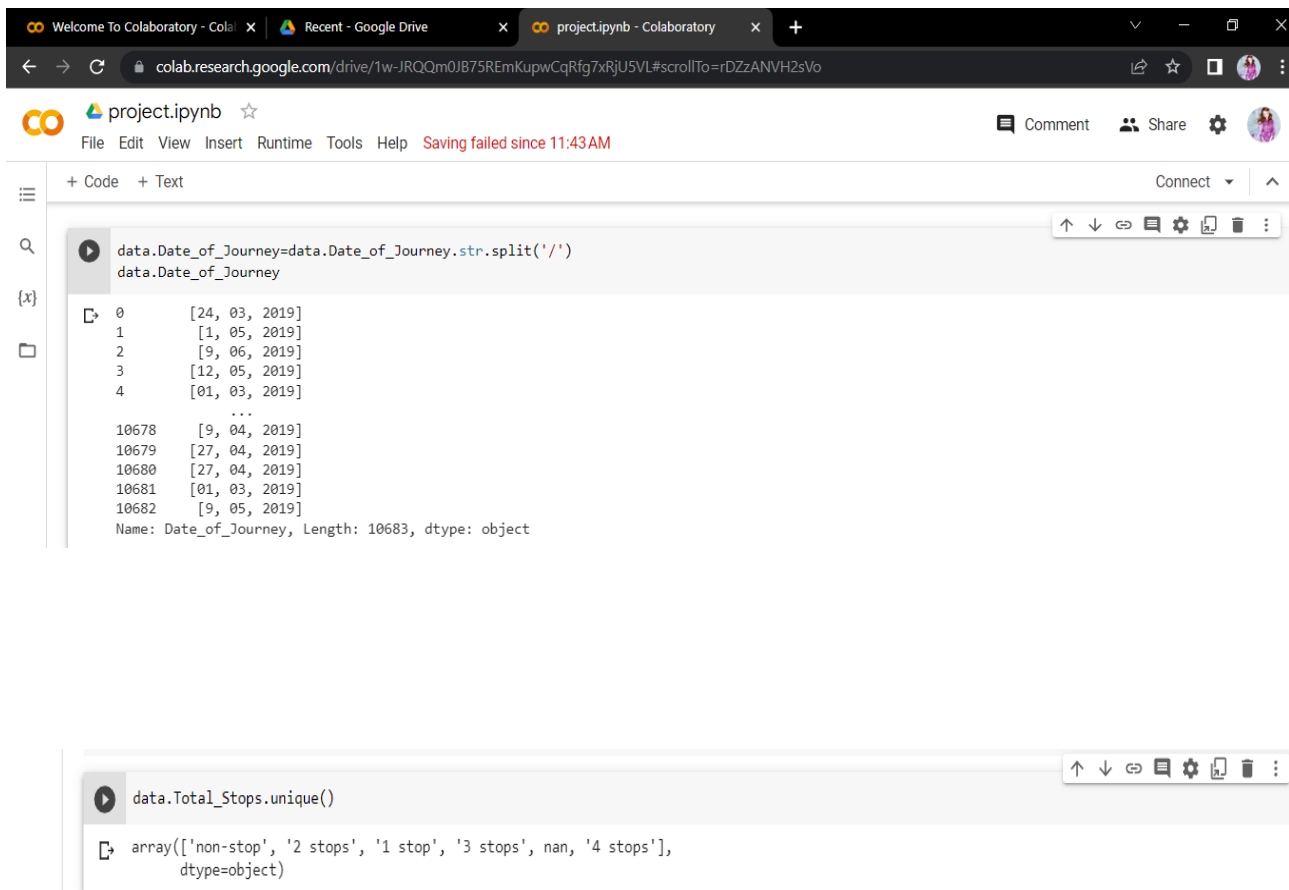

The screenshot shows a Google Colaboratory notebook interface. The browser tabs at the top include 'Welcome To Colaboratory - Colab', 'Recent - Google Drive', and 'project.ipynb - Colaboratory'. The address bar shows a Google Drive link. The notebook header includes the 'project.ipynb' logo, a star icon, and a menu bar with 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. A red status message says 'Saving failed since 11:43 AM'. The code cell contains a list of categories and a loop to print unique values for each. The output shows the unique values for each category.

```
category=['Airline','Source','Destination','Additional_Info']
for i in category:
    print(i, data[i].unique())
```

Airline ['IndiGo' 'Air India' 'Jet Airways' 'SpiceJet' 'Multiple carriers' 'GoAir'
'Vistara' 'Air Asia' 'Vistara Premium economy' 'Jet Airways Business'
'Multiple carriers Premium economy' 'Trujet']
Source ['Bangalore' 'Kolkata' 'Delhi' 'Chennai' 'Mumbai']
Destination ['New Delhi' 'Bangalore' 'Cochin' 'Kolkata' 'Delhi' 'Hyderabad']
Additional_Info ['No info' 'In-flight meal not included' 'No check-in baggage included'
'1 Short layover' 'No Info' '1 Long layover' 'Change airports'
'Business class' 'Red-eye flight' '2 Long layover']

Then split the dataframe:

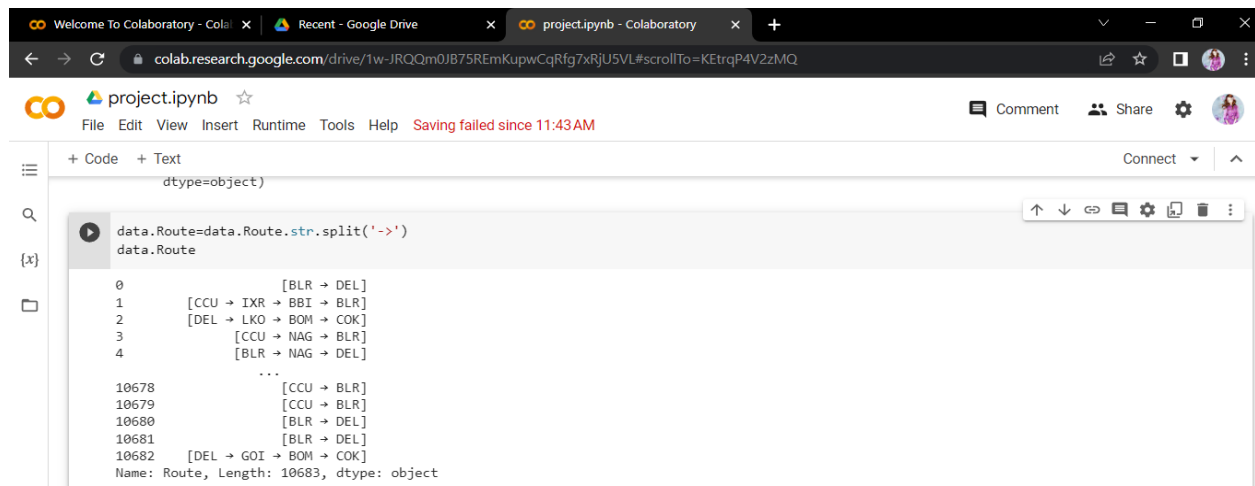

The screenshot shows a Google Colaboratory notebook interface. The browser tabs at the top include 'Welcome To Colaboratory - Colab', 'Recent - Google Drive', and 'project.ipynb - Colaboratory'. The address bar shows a Google Drive link. The notebook header includes the 'project.ipynb' logo, a star icon, and a menu bar with 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. A red status message says 'Saving failed since 11:43 AM'. The first code cell splits the 'Date_of_Journey' column by the '/' character. The output shows a list of date arrays. The second code cell finds the unique values of the 'Total_Stops' column. The output shows an array of stop counts.

```
data.Date_of_Journey=data.Date_of_Journey.str.split('/')
data.Date_of_Journey
```

0 [24, 03, 2019]
1 [1, 05, 2019]
2 [9, 06, 2019]
3 [12, 05, 2019]
4 [01, 03, 2019]
...
10678 [9, 04, 2019]
10679 [27, 04, 2019]
10680 [27, 04, 2019]
10681 [01, 03, 2019]
10682 [9, 05, 2019]
Name: Date_of_Journey, Length: 10683, dtype: object

```
data.Total_Stops.unique()
```

array(['non-stop', '2 stops', '1 stop', '3 stops', nan, '4 stops'],
 dtype=object)

The screenshot shows a Google Colaboratory notebook interface. The browser tabs at the top include 'Welcome To Colaboratory - Colab', 'Recent - Google Drive', and 'project.ipynb - Colaboratory'. The address bar shows a Google Drive link. The notebook's top bar includes the 'project.ipynb' logo, a star icon, and a red status message 'Saving failed since 11:43 AM'. The menu bar contains 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. The left sidebar has icons for file explorer, search, and variable explorer. The main code editor shows the following code and output:

```
dtype=object)

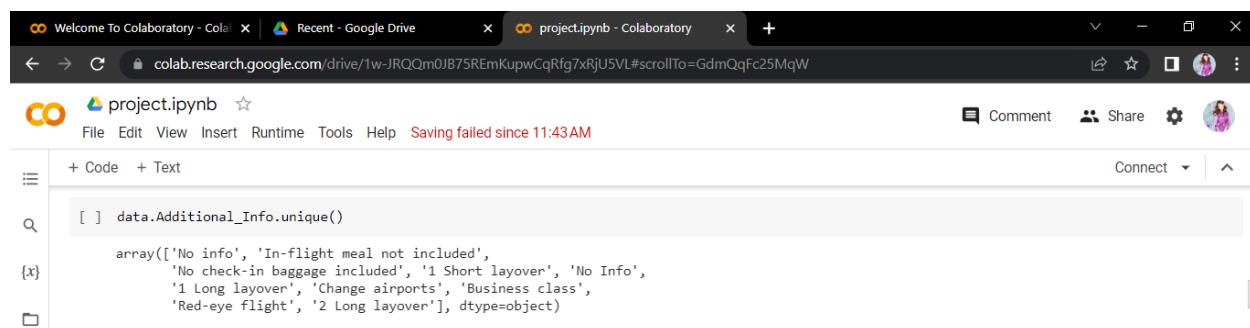

data.Route=data.Route.str.split('->')
data.Route
```

The output is a pandas DataFrame with 10683 rows and 1 column. The first few rows are:

0	[BLR → DEL]
1	[CCU → IXR → BBI → BLR]
2	[DEL → LKO → BOM → COK]
3	[CCU → NAG → BLR]
4	[BLR → NAG → DEL]
...	...
10678	[CCU → BLR]
10679	[CCU → BLR]
10680	[BLR → DEL]
10681	[BLR → DEL]
10682	[DEL → GOI → BOM → COK]

The bottom of the output shows: 'Name: Route, Length: 10683, dtype: object'.

Getting the information using info():

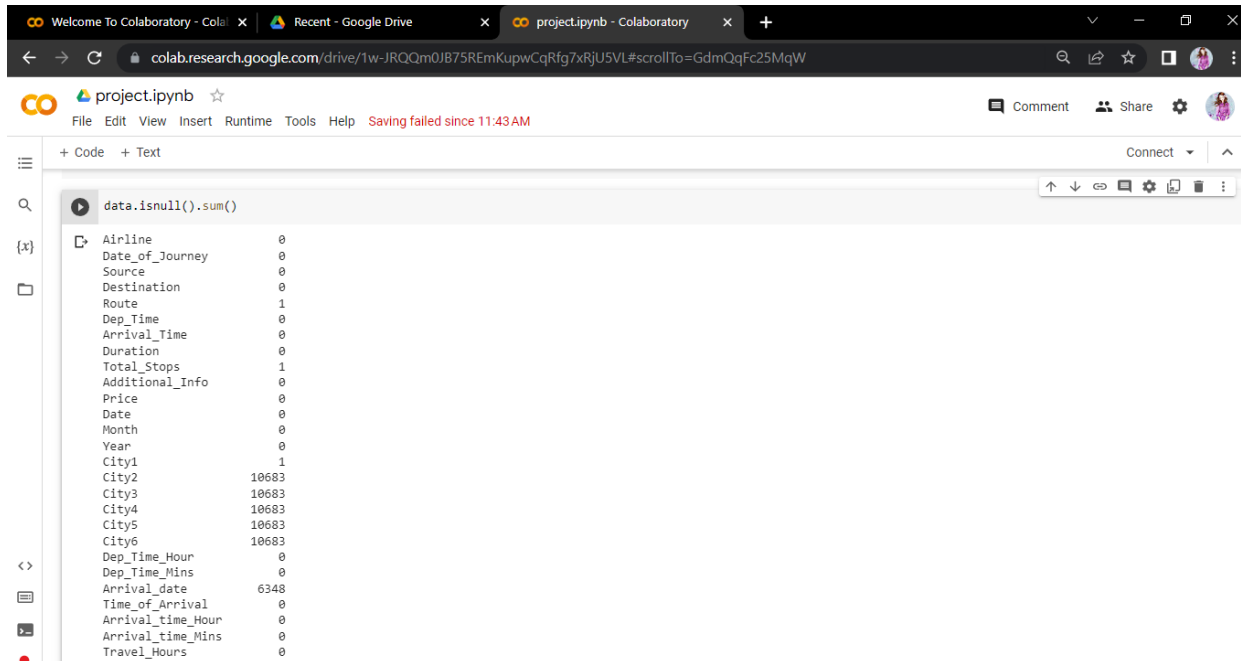

The screenshot shows a Google Colaboratory notebook interface. The browser tabs at the top include 'Welcome To Colaboratory - Colab', 'Recent - Google Drive', and 'project.ipynb - Colaboratory'. The address bar shows a Google Drive link. The notebook's top bar includes the 'project.ipynb' logo, a star icon, and a red status message 'Saving failed since 11:43 AM'. The menu bar contains 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. The left sidebar has icons for file explorer, search, and variable explorer. The main code editor shows the following code and output:

```
[ ] data.Additional_Info.unique()
```

The output is a pandas Series with the following unique values:

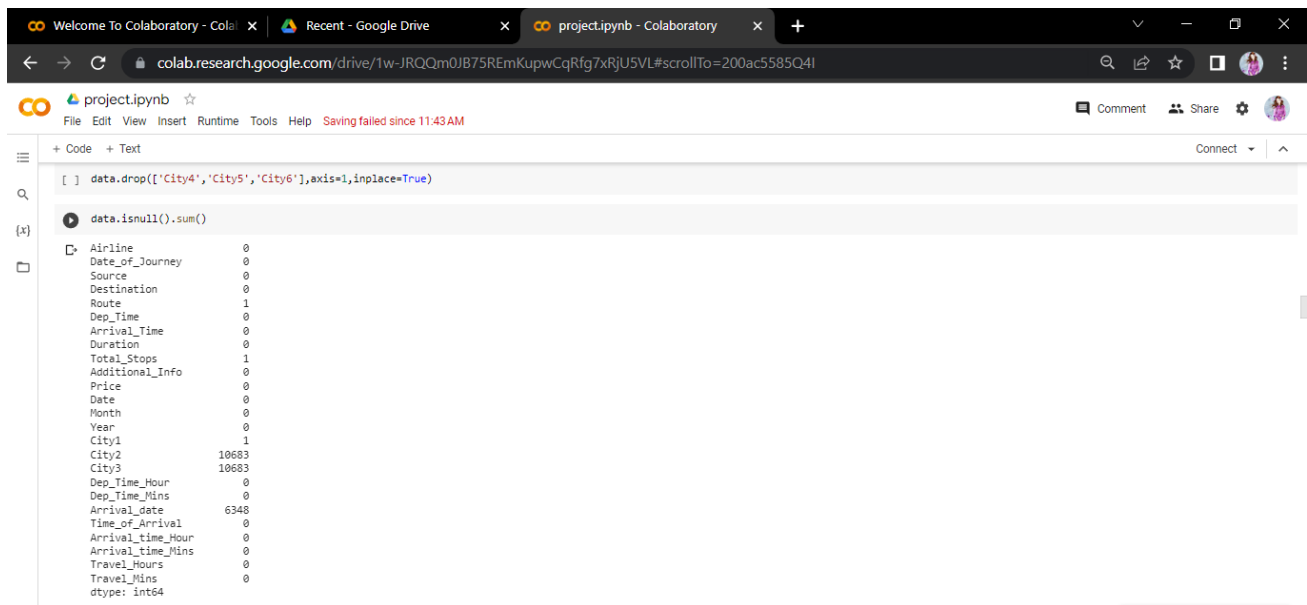

```
array(['No info', 'In-flight meal not included',  
      'No check-in baggage included', '1 Short layover', 'No Info',  
      '1 Long layover', 'Change airports', 'Business class',  
      'Red-eye flight', '2 Long layover'], dtype=object)
```

Finding sum of Null Values isnull().sum() function:

The screenshot shows the Google Colaboratory interface. The browser tabs include 'Welcome To Colaboratory - Colab', 'Recent - Google Drive', and 'project.ipynb - Colaboratory'. The address bar shows the URL: `colab.research.google.com/drive/1w-JRQQm0JB75REmKupwCqRfg7xRjU5VL#scrollTo=GdmQqFc25MqW`. The project.ipynb file is open, and the 'Code' tab is selected. The code cell contains the command `data.isnull().sum()`. The output is a series of columns and their corresponding null counts.

Column	Count

Change the data type of the required columns:

The screenshot shows a Google Colab notebook interface. The browser tabs include 'Welcome To Colaboratory - Colab', 'Recent - Google Drive', and 'project.ipynb - Colaboratory'. The URL bar shows a Google Drive link. The notebook's top bar includes the 'project.ipynb' title, a star icon, and a menu with 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. A red status message reads 'Saving failed since 11:43 AM'. On the right, there are icons for 'Comment', 'Share', and a user profile. The main code editor area has a toolbar with '+ Code' and '+ Text' buttons, and a 'Connect' button. The code being executed is as follows:

```
[ ] #changing the numerical columns from object to int
#data.Total_Stops=data.Total_Stops.astype('int64')
data.Date=data.Date.astype('int64')
data.Month=data.Month.astype('int64')
data.Year=data.Year.astype('int64')
data.Dep_Time_Hour=data.Dep_Time_Hour.astype('int64')
data.Dep_Time_Hour=data.Dep_Time_Hour.astype('int64')
data.Dep_Time_Mins=data.Dep_Time_Mins.astype('int64')
data.Arrival_date=data.Arrival_date.astype('int64')
data.Arrival_Time_Hour=data.Arrival_time_Hour.astype('int64')
data.Arrival_Time_Mins=data.Arrival_time_Mins.astype('int64')
#data.Total_Stops=data.Total_Stops.astype('int64')
data.Travel_Mins=data.Travel_Mins.astype('int64')
```

The screenshot shows the same Google Colab notebook interface. The browser tabs and URL are the same. The notebook's top bar and status message are also the same. The main code editor area shows the following code:

```
[ ] data.Travel_Mins=data.Travel_Mins.astype('int64')
[ ] data[data['Travel_Hours']=='5m']
```

Below the code, a data preview table is displayed. The table has 15 columns: 'Airline', 'Date_of_Journey', 'Source', 'Destination', 'Route', 'Dep_Time', 'Arrival_Time', 'Duration', 'Total_Stops', 'Additional_Info', '...', 'City2', 'City3', 'Dep_Time_Hour', 'Dep_Time_Mins', 'Arrival_date', 'Time_of_Arrival', 'Arrival_time_Hour', and 'Arrival_'. The first row of data is empty, and the second row shows '0 rows x 25 columns'. At the bottom, a status message reads 'data.droo(index=6474,inplace=True,axis=0)'.

Label Encoding:

project.ipynb

```
[ ] from sklearn.preprocessing import LabelEncoder
le=LabelEncoder()

data.Airline = le.fit_transform(data.Airline)
data.Source = le.fit_transform(data.Source)
data.Destination = le.fit_transform(data.Destination)
data.City1 = le.fit_transform(data.City1)
data.City2 = le.fit_transform(data.City2)
data.City3 = le.fit_transform(data.City3)
data.Additional_Info = le.fit_transform(data.Additional_Info)
```

```
[ ] data.head()
```

DATA ANALYSIS

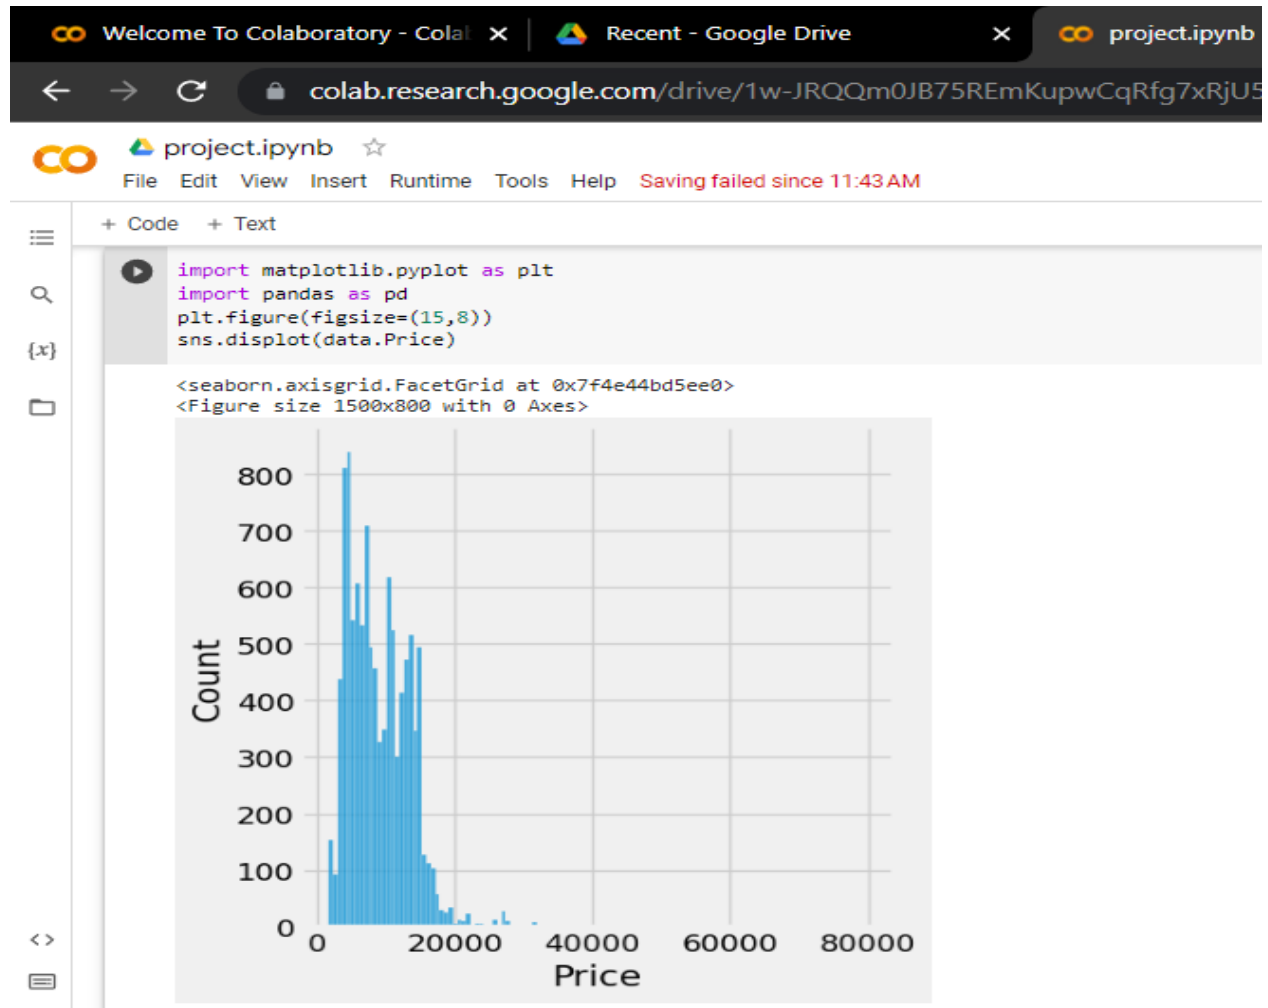

○ Descriptive Analysis:

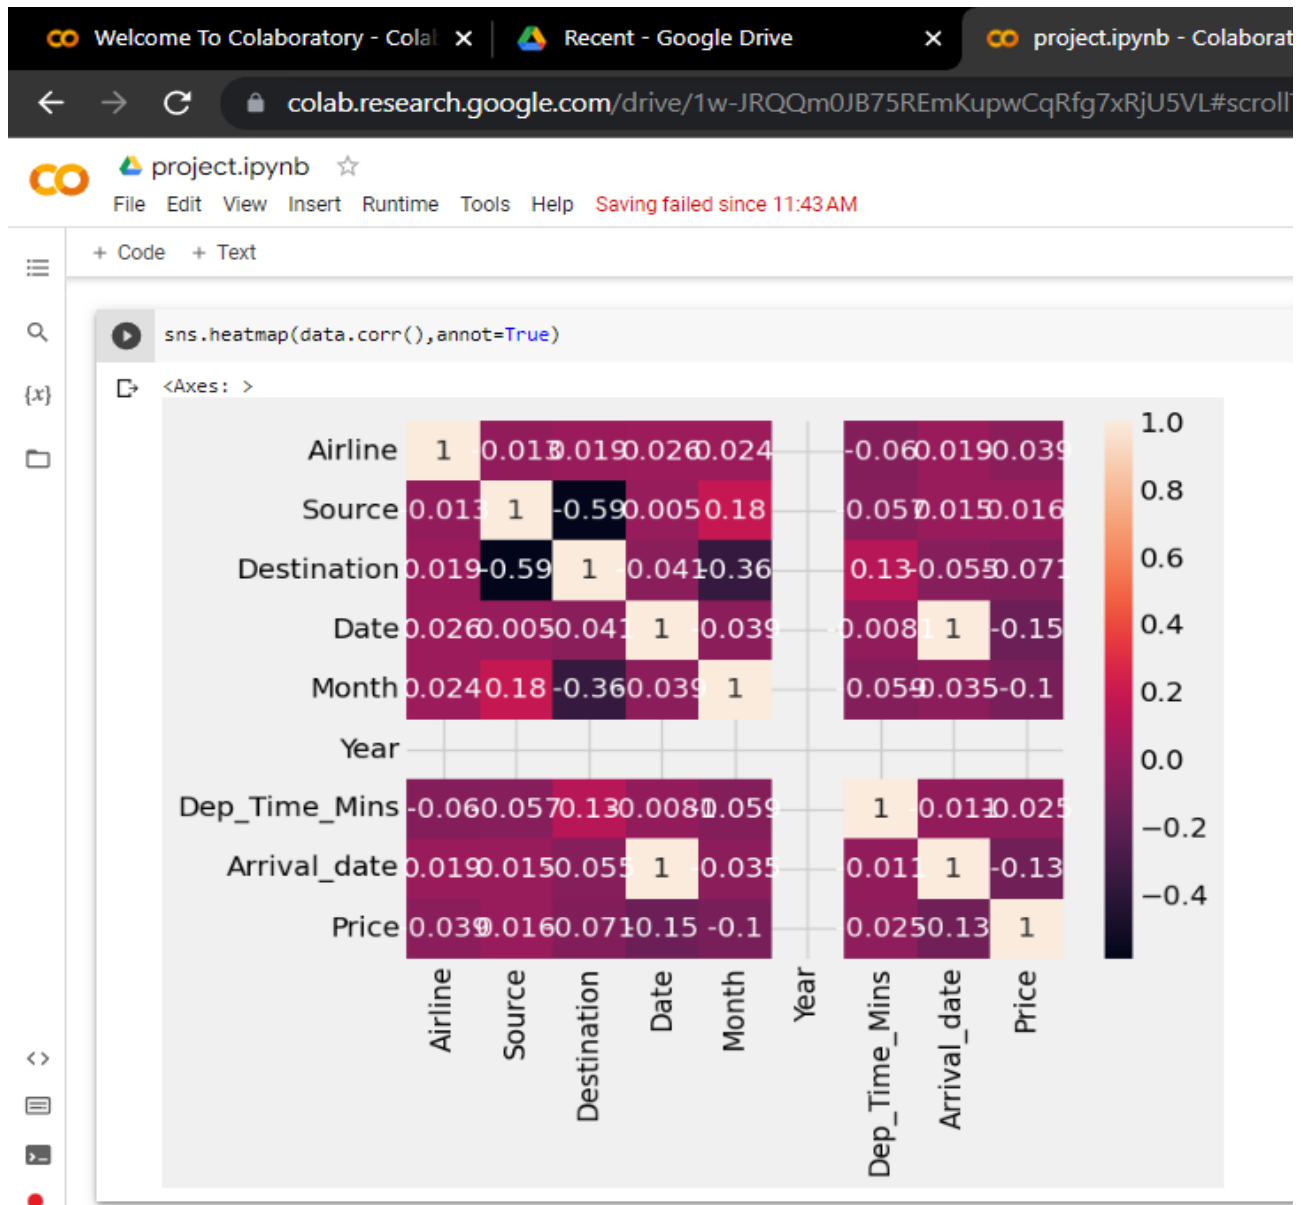

○ Visual Analysis:

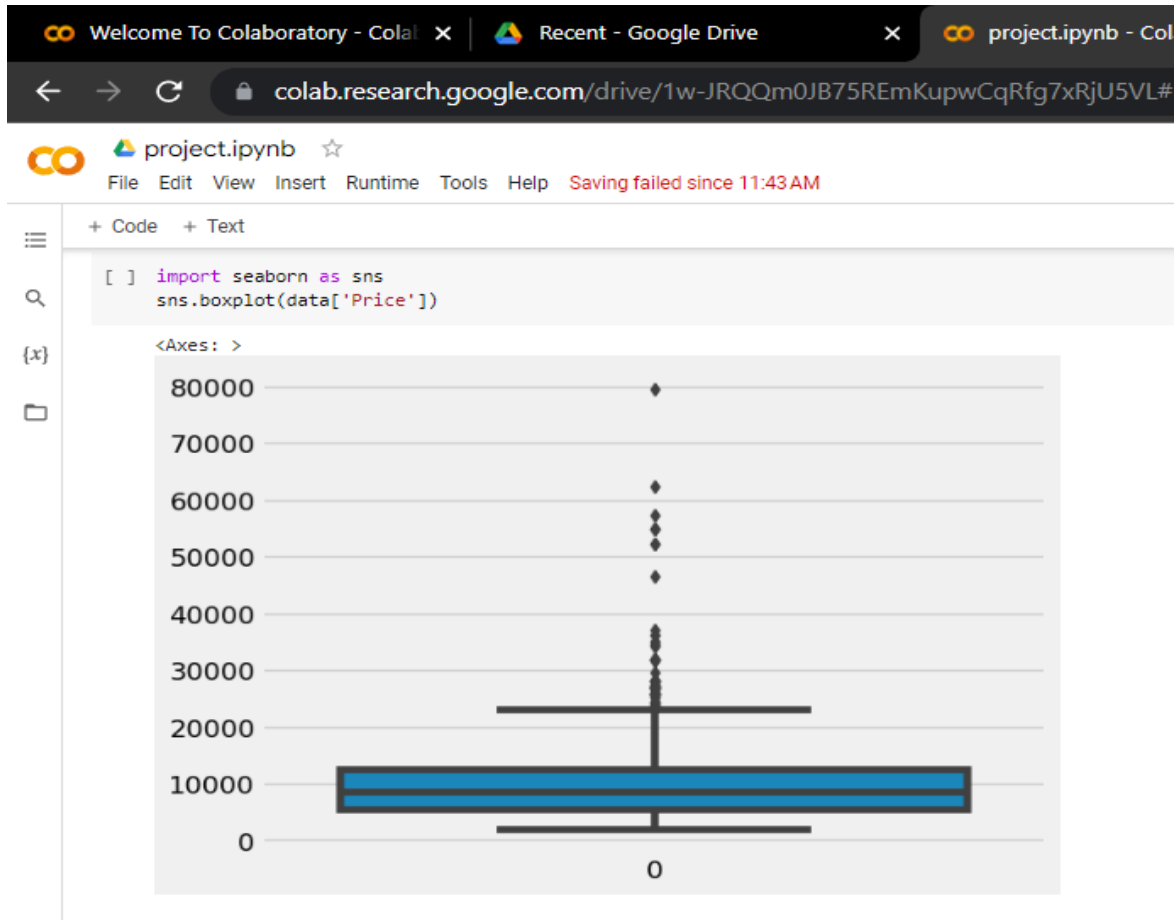

○ Univariate analysis

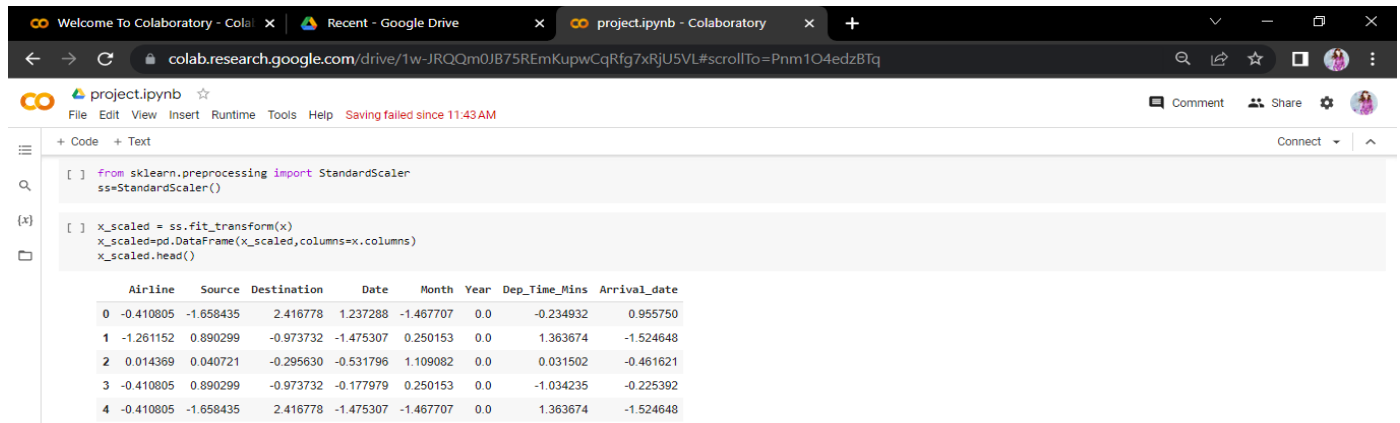

○ Using Heat Map:

Finding outliers:

Scale the Data:

The screenshot shows the Google Colaboratory interface with a code cell containing the following Python code:

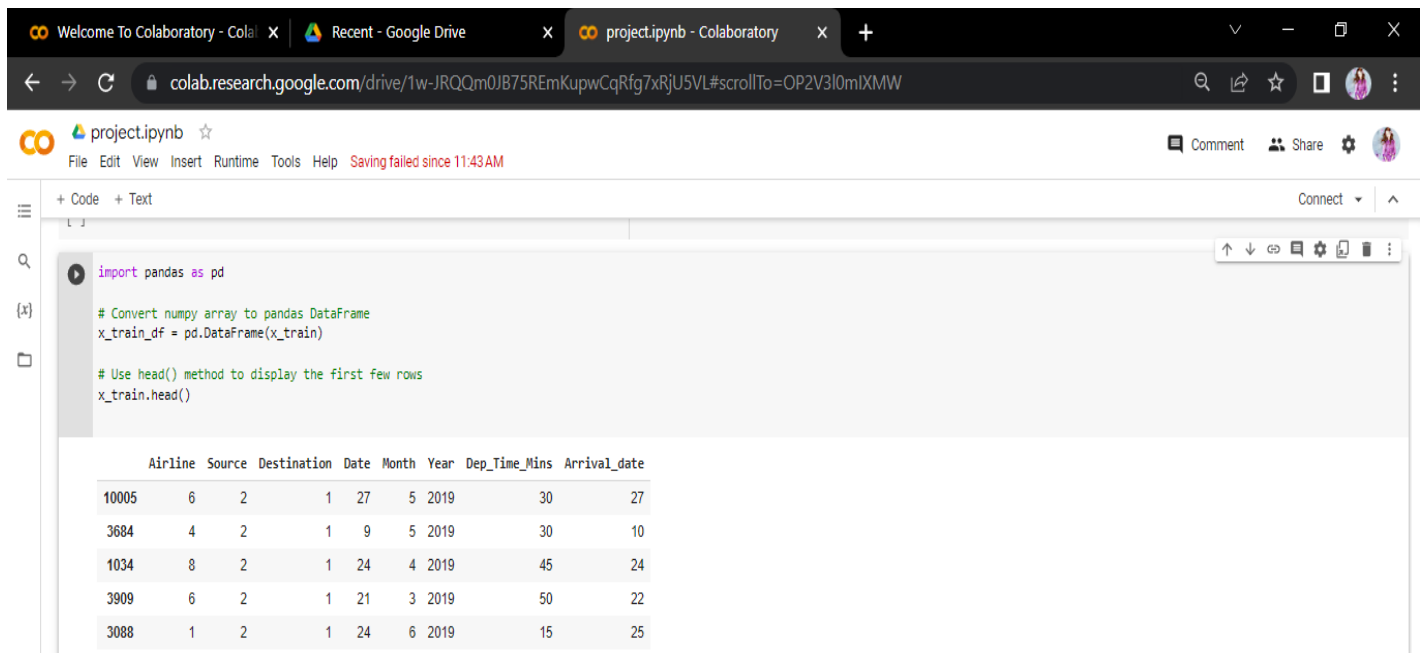

```
[ ] from sklearn.preprocessing import StandardScaler
    ss=StandardScaler()

[ ] x_scaled = ss.fit_transform(x)
    x_scaled=pd.DataFrame(x_scaled,columns=x.columns)
    x_scaled.head()
```

The output of the code is a DataFrame with 5 rows and 9 columns:

	Airline	Source	Destination	Date	Month	Year	Dep_Time_Mins	Arrival_date
0	-0.410805	-1.658435	2.416778	1.237288	-1.467707	0.0	-0.234932	0.955750
1	-1.261152	0.890299	-0.973732	-1.475307	0.250153	0.0	1.363674	-1.524648
2	0.014369	0.040721	-0.295630	-0.531796	1.109082	0.0	0.031502	-0.461621
3	-0.410805	0.890299	-0.973732	-0.177979	0.250153	0.0	-1.034235	-0.225392
4	-0.410805	-1.658435	2.416778	-1.475307	-1.467707	0.0	1.363674	-1.524648

Splitting data into train and test:

The screenshot shows the Google Colaboratory interface with a code cell containing the following Python code:

```
[ ] import pandas as pd

[ ] # Convert numpy array to pandas DataFrame
    x_train_df = pd.DataFrame(x_train)

[ ] # Use head() method to display the first few rows
    x_train.head()
```

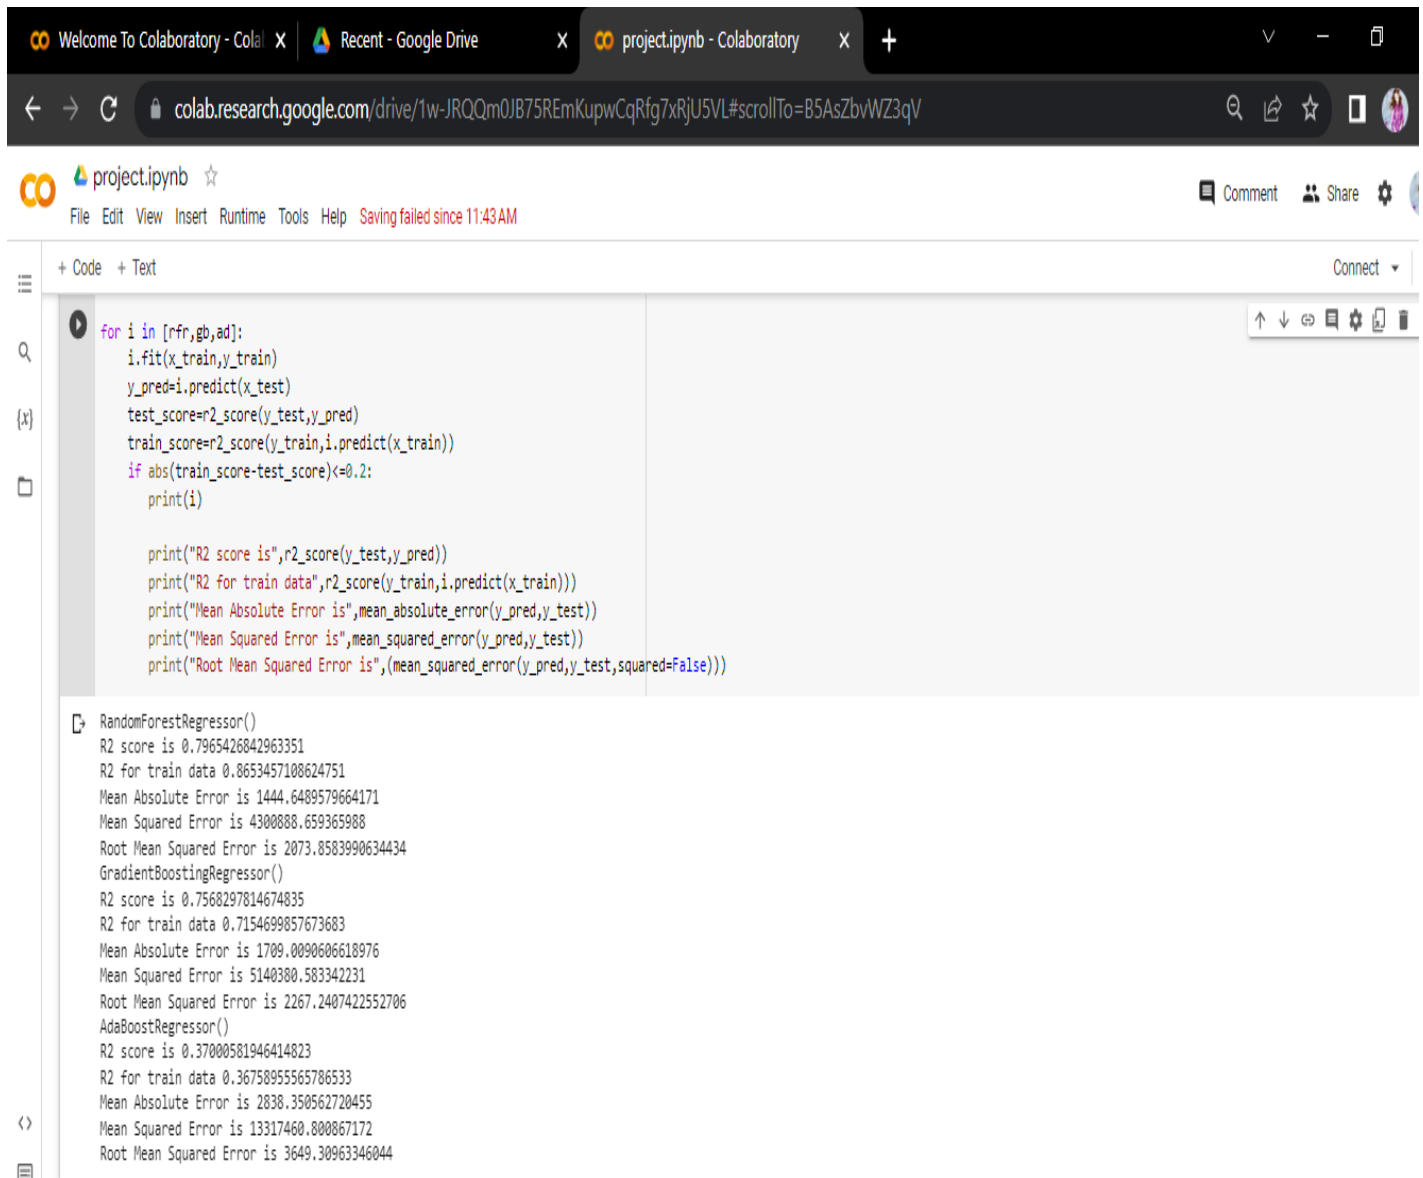

The output of the code is a DataFrame with 5 rows and 9 columns:

	Airline	Source	Destination	Date	Month	Year	Dep_Time_Mins	Arrival_date
10005	6	2	1	27	5	2019	30	27
3684	4	2	1	9	5	2019	30	10
1034	8	2	1	24	4	2019	45	24
3909	6	2	1	21	3	2019	50	22
3088	1	2	1	24	6	2019	15	25

MODEL BUILDING

Applying algorithms

❖ Random Forest Regressor:

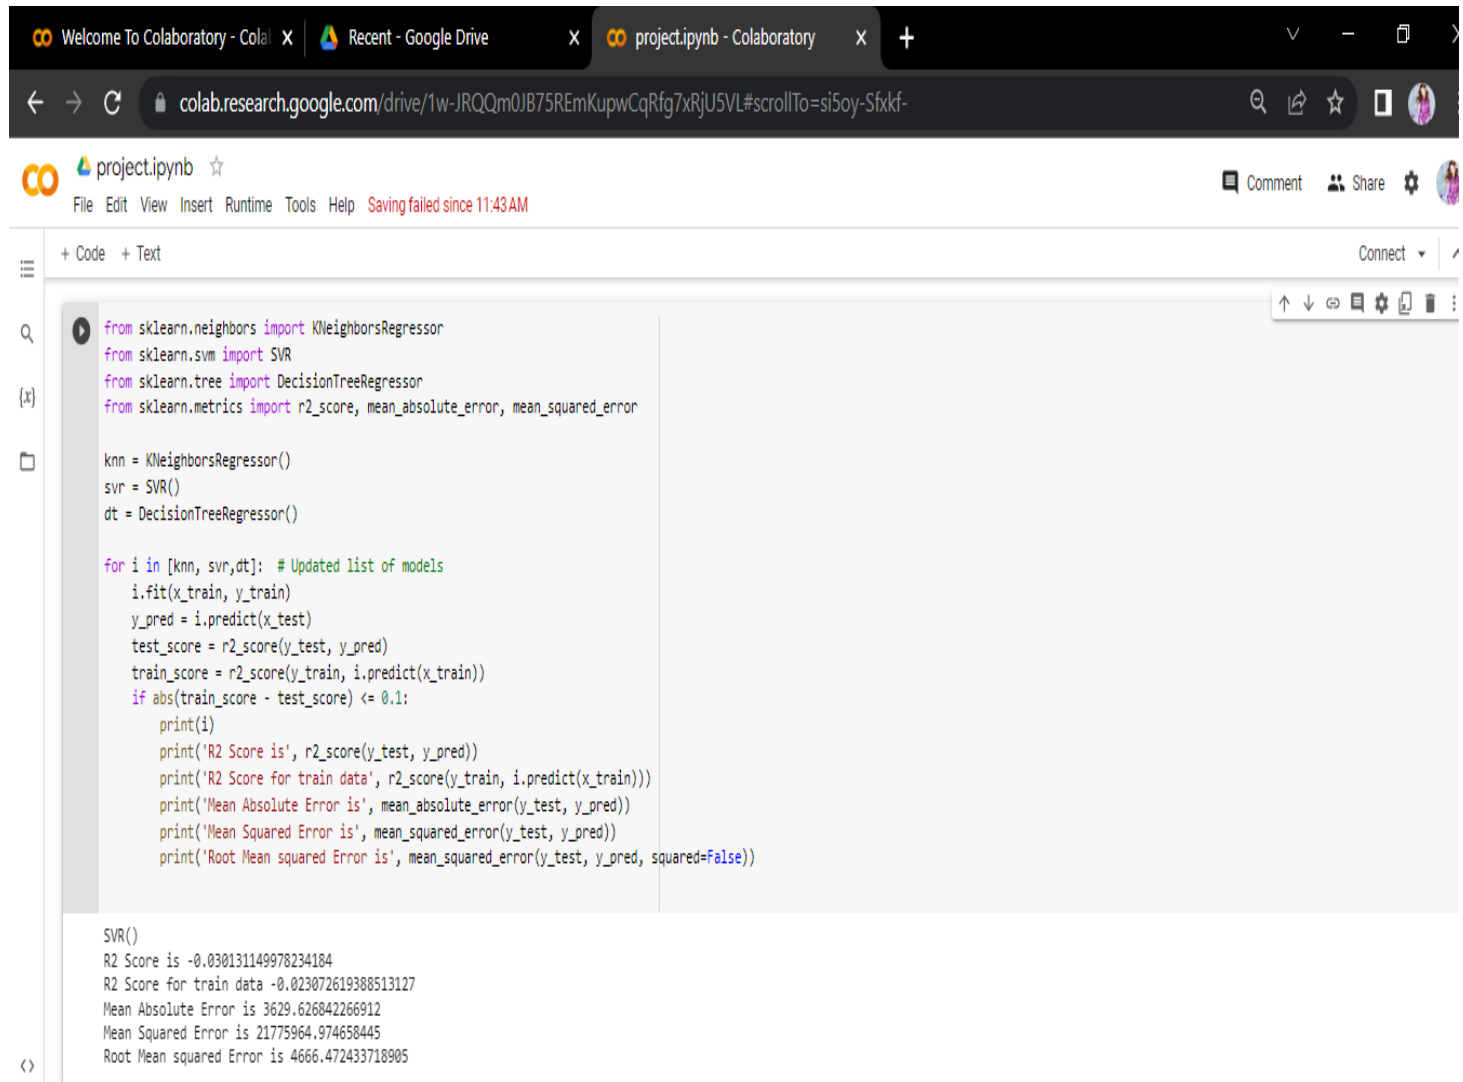

```
for i in [rfr,gb,ad]:
    i.fit(x_train,y_train)
    y_pred=i.predict(x_test)
    test_score=r2_score(y_test,y_pred)
    train_score=r2_score(y_train,i.predict(x_train))
    if abs(train_score-test_score)<=0.2:
        print(i)

        print("R2 score is",r2_score(y_test,y_pred))
        print("R2 for train data",r2_score(y_train,i.predict(x_train)))
        print("Mean Absolute Error is",mean_absolute_error(y_pred,y_test))
        print("Mean Squared Error is",mean_squared_error(y_pred,y_test))
        print("Root Mean Squared Error is",(mean_squared_error(y_pred,y_test,squared=False)))

RandomForestRegressor()
R2 score is 0.7965426842963351
R2 for train data 0.8653457108624751
Mean Absolute Error is 1444.6489579664171
Mean Squared Error is 4300888.659365908
Root Mean Squared Error is 2073.8583990634434
GradientBoostingRegressor()
R2 score is 0.7568297814674835
R2 for train data 0.7154699857673683

R2 for train data 0.36758955565786533
Mean Absolute Error is 2838.350562720455
Mean Squared Error is 13317460.800867172
Root Mean Squared Error is 3649.30963346044
```

❖ K Neighbors Regressor

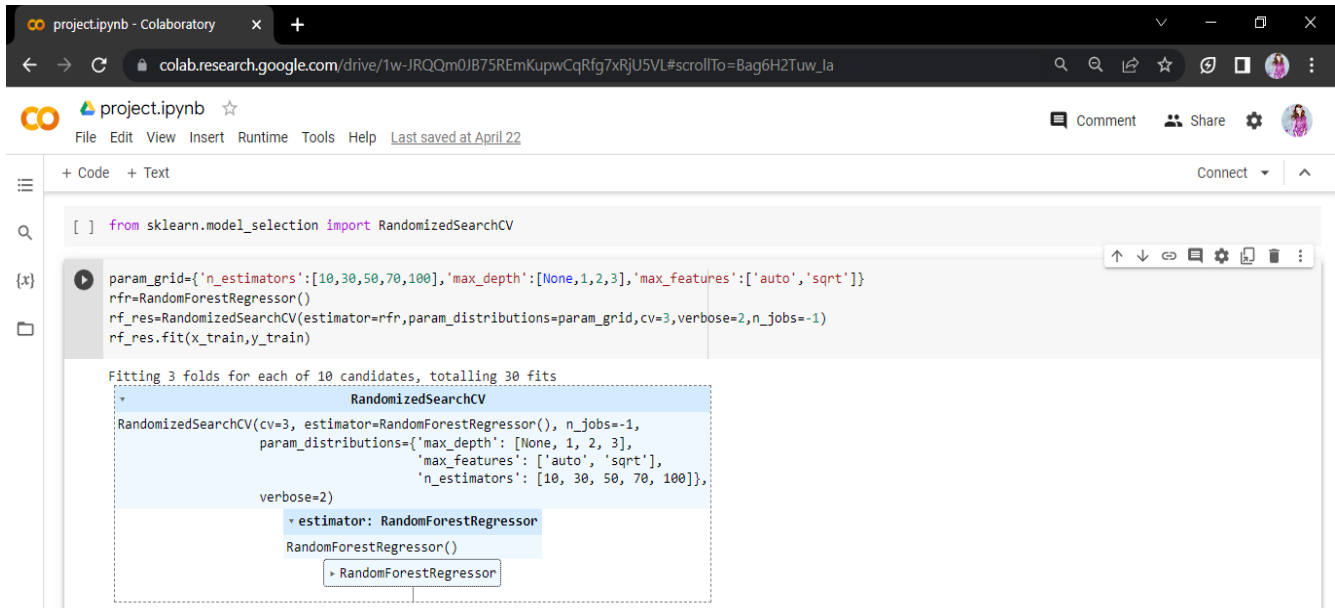

```
from sklearn.neighbors import KNeighborsRegressor
from sklearn.svm import SVR
from sklearn.tree import DecisionTreeRegressor
from sklearn.metrics import r2_score, mean_absolute_error, mean_squared_error

knn = KNeighborsRegressor()
svr = SVR()
dt = DecisionTreeRegressor()

for i in [knn, svr, dt]: # Updated list of models
    i.fit(x_train, y_train)
    y_pred = i.predict(x_test)
    test_score = r2_score(y_test, y_pred)
    train_score = r2_score(y_train, i.predict(x_train))
    if abs(train_score - test_score) <= 0.1:
        print(i)
        print('R2 Score is', r2_score(y_test, y_pred))
        print('R2 Score for train data', r2_score(y_train, i.predict(x_train)))
        print('Mean Absolute Error is', mean_absolute_error(y_test, y_pred))
        print('Mean Squared Error is', mean_squared_error(y_test, y_pred))
        print('Root Mean squared Error is', mean_squared_error(y_test, y_pred, squared=False))

SVR()
R2 Score is -0.030131149978234184
R2 Score for train data -0.023072619388513127
Mean Absolute Error is 3629.626842266912
Mean Squared Error is 21775964.974658445
Root Mean squared Error is 4666.472433718905
```

Checking Cross Validation for Random Forest Regressor

The screenshot shows a Jupyter Notebook interface in Google Colaboratory. The code cell contains the following Python code:

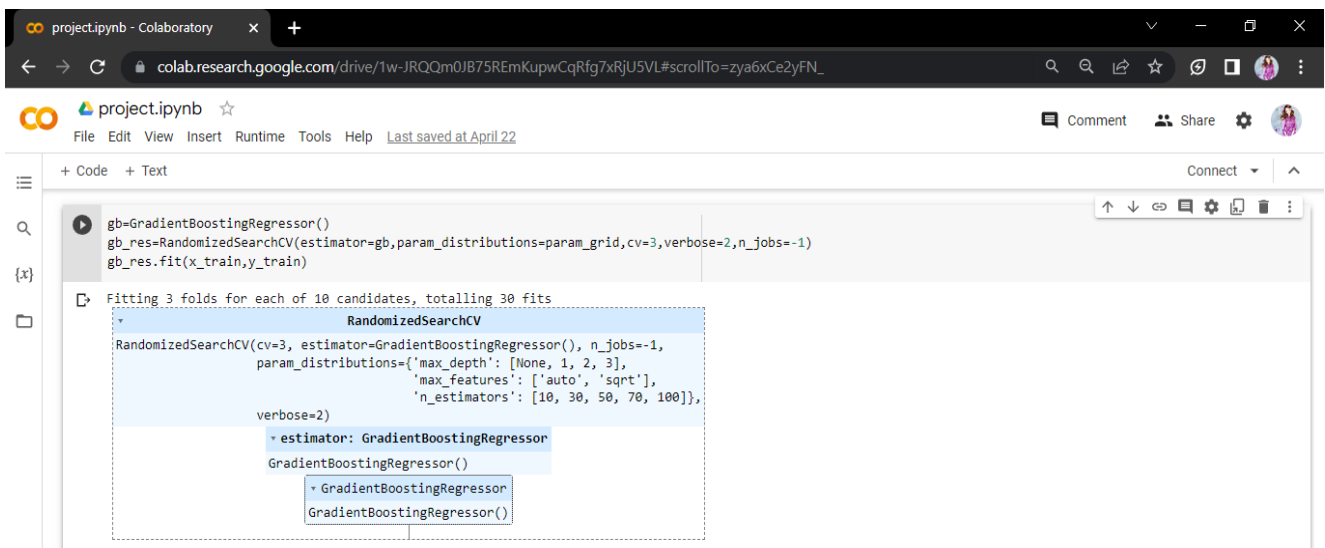

```
[ ] from sklearn.model_selection import RandomizedSearchCV

param_grid={'n_estimators':[10,30,50,70,100], 'max_depth':[None,1,2,3], 'max_features':['auto', 'sqrt']}
rfr=RandomForestRegressor()
rf_res=RandomizedSearchCV(estimator=rfr, param_distributions=param_grid, cv=3, verbose=2, n_jobs=-1)
rf_res.fit(x_train, y_train)
```

Below the code, the output shows the fitting process for the Random Forest Regressor:

```
Fitting 3 folds for each of 10 candidates, totalling 30 fits
RandomizedSearchCV
RandomizedSearchCV(cv=3, estimator=RandomForestRegressor(), n_jobs=-1,
  param_distributions={'max_depth': [None, 1, 2, 3],
    'max_features': ['auto', 'sqrt'],
    'n_estimators': [10, 30, 50, 70, 100]},
  verbose=2)
  estimator: RandomForestRegressor
    RandomForestRegressor()
```

❖ Gradient Boosting Regressor

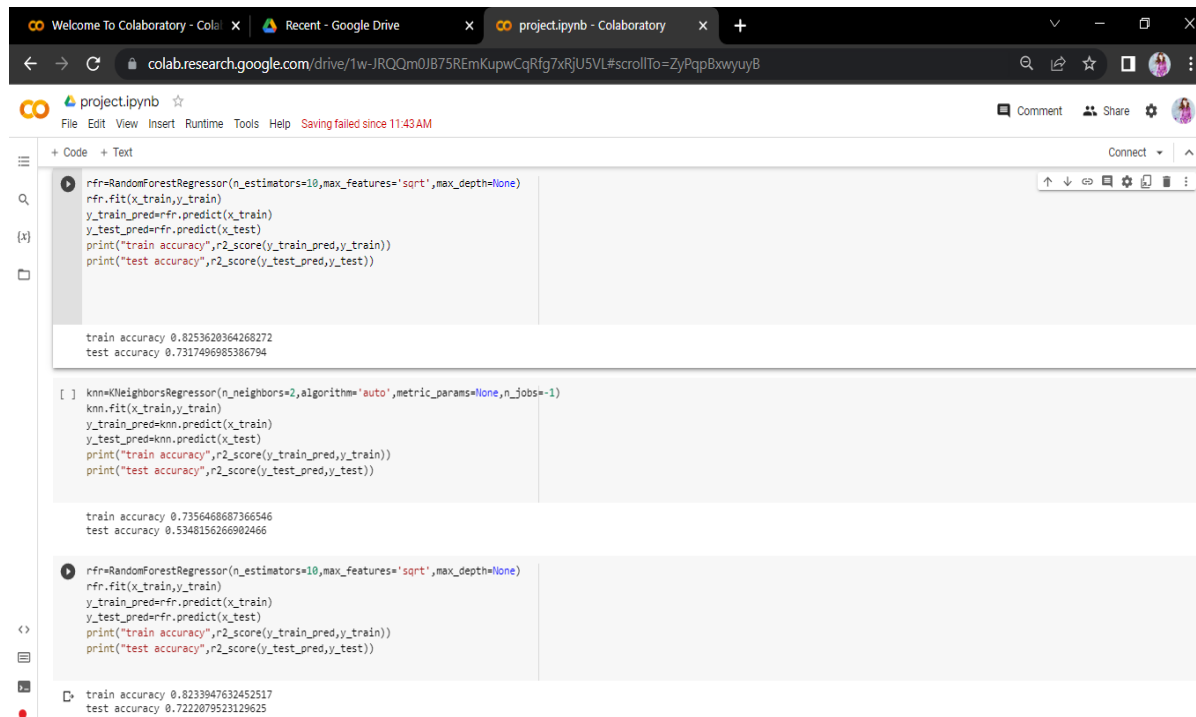

The screenshot shows a Jupyter Notebook interface in Google Colaboratory. The code cell contains the following Python code:

```
gb=GradientBoostingRegressor()
gb_res=RandomizedSearchCV(estimator=gb, param_distributions=param_grid, cv=3, verbose=2, n_jobs=-1)
gb_res.fit(x_train, y_train)
```

Below the code, the output shows the fitting process for the Gradient Boosting Regressor:

```
Fitting 3 folds for each of 10 candidates, totalling 30 fits
RandomizedSearchCV
RandomizedSearchCV(cv=3, estimator=GradientBoostingRegressor(), n_jobs=-1,
  param_distributions={'max_depth': [None, 1, 2, 3],
    'max_features': ['auto', 'sqrt'],
    'n_estimators': [10, 30, 50, 70, 100]},
  verbose=2)
  estimator: GradientBoostingRegressor
    GradientBoostingRegressor()
      GradientBoostingRegressor()
```

Accuracy

```
rfr=RandomForestRegressor(n_estimators=10,max_features='sqrt',max_depth=None)
rfr.fit(x_train,y_train)
y_train_pred=rfr.predict(x_train)
y_test_pred=rfr.predict(x_test)
print("train accuracy",r2_score(y_train_pred,y_train))
print("test accuracy",r2_score(y_test_pred,y_test))

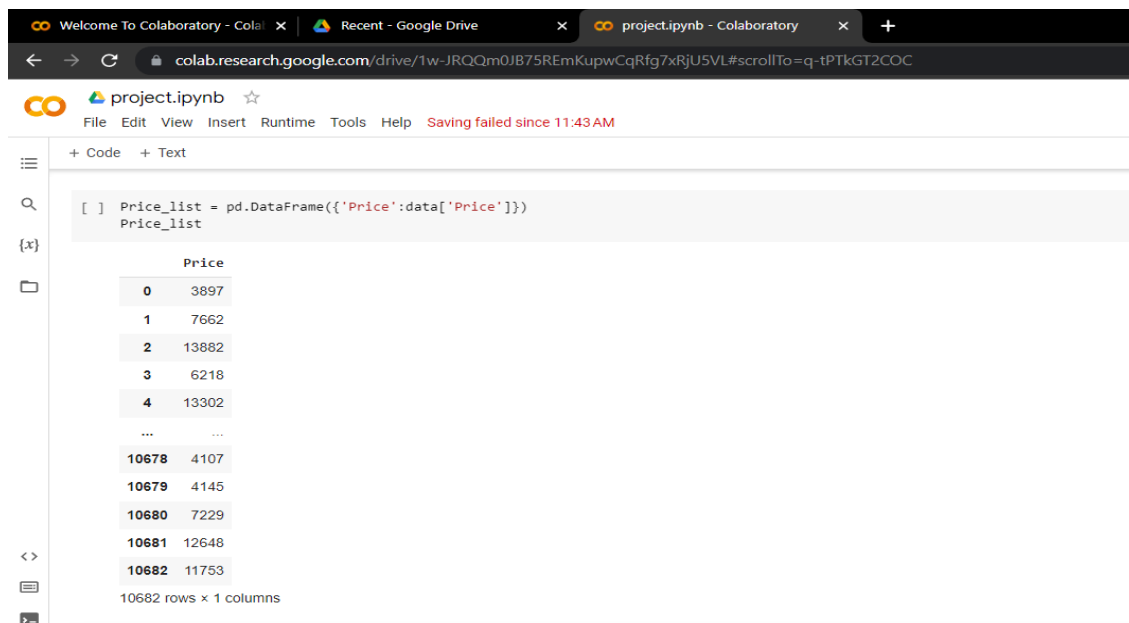

train accuracy 0.8253620364268272
test accuracy 0.7317496985386794

[ ] knn=KNeighborsRegressor(n_neighbors=2,algorithm='auto',metric_params=None,n_jobs=-1)
knn.fit(x_train,y_train)
y_train_pred=knn.predict(x_train)
y_test_pred=knn.predict(x_test)
print("train accuracy",r2_score(y_train_pred,y_train))
print("test accuracy",r2_score(y_test_pred,y_test))

train accuracy 0.7356468687366546
test accuracy 0.5348156266902466

rfr=RandomForestRegressor(n_estimators=10,max_features='sqrt',max_depth=None)
rfr.fit(x_train,y_train)
y_train_pred=rfr.predict(x_train)
y_test_pred=rfr.predict(x_test)
print("train accuracy",r2_score(y_train_pred,y_train))
print("test accuracy",r2_score(y_test_pred,y_test))

train accuracy 0.8233947632452517
test accuracy 0.7222079523129625
```

10681	12648
10682	11753

10682 rows x 1 columns

Advantages & Disadvantages

Advantages:

Cost Savings: One of the primary advantages of flight price prediction is that it can help travelers save money. By predicting when prices are likely to be at their lowest, travelers can book their flights at the optimal time and avoid overpaying for their tickets.

predicting flight prices in advance, users can make more informed decisions about when to book their flights, potentially saving money on their travel expenses.

Time savings: Flight price prediction can save travelers a significant amount of time by helping them quickly identify the best times to book their flights. This can be particularly useful for people who need to travel frequently for work or other reasons.

Accuracy: Machine learning algorithms can process large amounts of historical data and identify patterns that humans may not be able to see, resulting in more accurate predictions.

Efficiency: Predicting flight prices using machine learning can be much faster and more efficient than manually analyzing data.

Convenience: Flight price prediction tools are often easy to use and can be accessed from a variety of devices, including smartphones and tablets. This makes it convenient for travelers to check flight prices and make bookings on the go.

Increased accessibility: Flight price prediction makes air travel more accessible to a wider range of people by helping them find affordable flights. By predicting price changes and providing cost-saving opportunities, more people can afford to fly, opening up new opportunities for travel and business.

Enhanced customer experience:

By providing travelers with valuable information about pricing trends and helping them find the best deals, flight price prediction can improve the overall customer experience. This can lead to increased customer satisfaction and loyalty, as well as positive word-of-mouth recommendations.

Improved revenue management: Flight price prediction can benefit airlines by enabling them to optimize their revenue management strategies. By accurately forecasting demand and pricing trends, airlines can adjust their prices in real-time to maximize revenue and profitability.

Disadvantages

Inaccuracy: Flight booking price prediction is not Always accurate, and travelers may end up paying more than predicted if prices increase unexpectedly.

Data Availability: The accuracy of the predictions depends on the availability and quality of historical flight data. In some cases, data may not be readily available or may be incomplete, which can impact the accuracy of the predictions.

Model Complexity: Building a machine learning model for flight price prediction can be complex, requiring advanced programming skills and a good

understanding of machine learning algorithms.

Limited Scope: The model may not be able to account for all factors that can impact flight prices, such as sudden changes in fuel prices or political events that can affect air travel.

Unforeseen Factors: The model may not be able to predict unforeseen events, such as natural disasters, which can impact flight prices and availability.

Applications

Historical Data: The application can use historical flight data to predict future prices. This can include factors such as seasonality, airline demand, and holiday travel trends.

Price Alerts: Users can set up price alerts for specific flights, which notify them when the price drops below a certain threshold.

Price Trends: Users can view price trends over time for a particular route, and the application can provide recommendations on when to book to get the best price.

Fare Calendar: The application can display a fare calendar, which shows the lowest prices for a particular route over a range of dates.

Travel Budgeting: The application can help users plan their travel budget by providing an estimate of the total cost of a trip, including airfare, accommodations, and other expenses.

Travel Planning: The application can suggest alternative routes or travel dates to help users find the best deal.

Travel booking websites: Online travel agencies and booking websites can use machine learning algorithms to predict flight prices, and offer personalized recommendations to customers.

Airlines: Airlines can use machine learning algorithms to predict demand for flights, adjust prices accordingly, and optimize revenue management.

Travel agencies: Travel agencies can use machine learning algorithms to predict the prices of flights, and offer customized travel packages to customers.

Corporate travel management: Companies can use machine learning algorithms to predict flight prices and optimize travel expenses.

Price comparison websites: Price comparison websites can use machine learning algorithms to provide real-time

flight price comparisons across multiple airlines.

Travel apps: Travel apps can use machine learning algorithms to provide users with real-time flight prices and alerts when prices change.

conclusion

Flight price prediction using machine learning is an innovative solution that can benefit the travel industry in numerous ways.

With the help of machine learning algorithms, airlines, travel agencies, booking websites, and consumers can gain more accurate insights into flight prices, enabling them to make better decisions about travel plans and expenses.

By leveraging historical data, machine learning models can identify patterns and predict future prices, optimizing revenue management and enhancing the customer experience.

As machine learning technology continues to evolve, we can expect even more sophisticated

flight price prediction models to emerge, providing even greater value to the travel industry.

Overall, flight price prediction using machine learning has the potential to revolutionize the way we plan and book travel, making it more efficient, affordable, and enjoyable for everyone involved.

Future Scope

The scope for flight price prediction using machine learning algorithms is quite promising, and there are several areas where it could be expanded in the future:

Improved accuracy: As more data becomes available and machine learning algorithms become more sophisticated, the accuracy of flight price prediction models is likely to improve.

Personalized pricing: Machine learning algorithms could be used to create personalized

pricing models for individual travelers based on their past travel patterns, preferences, and behavior.

Real-time prediction: Real-time prediction models could be developed that use data such as weather conditions, flight delays, and passenger volume to adjust prices in real-time and provide travelers with the most up-to-date information on flight prices.

Integration with other travel-related services: Flight price prediction models could be integrated with other travel-related services such as hotel bookings and car rentals to provide travelers with a more comprehensive and seamless travel experience.

Expansion to other modes of transport: The same machine learning techniques used for flight price prediction could be applied to other modes of transport such as trains and buses, providing travelers with more options and flexibility when planning their journeys.

<p id="price_result">

```

The objective of this article is to predict flight prices given the various parameters. This will be regression problem since the target or dependent variable is the price (continuous numeric value). Nowadays, the number of people using flights has increased significantly. It is difficult for airlines to maintain prices since prices change dynamically due to different conditions. That's why we will try to use machine learning to solve this problem. This can help airlines by predicting what prices they can maintain. It can help customers to predict future flight prices and plan their journey accordingly.
